NOTICE TO ACCOMPANY THE DISSEMINATION OF EXPORT-CONTROLLED TECHNICAL DATA

- 1. Export of information contained herein, which includes, in some circumstances, release to foreign nationals within the United States, without first obtaining approval or license from the Department of State for items controlled by the International Traffic in Arms Regulations (ITAR), or the Department of Commerce for items controlled by the Export Administration Regulations (EAR), may constitute a violation of law.
- 2. Under 22 U.S.C. 2778 the penalty for unlawful export of items or information controlled under the ITAR is up to 2 years imprisonment, or a fine of \$100,000 or both. Under 50 U.S.C., Appendix 2410, the penalty for unlawful export of items or information controlled under the EAR is a fine of up to \$1,000,000 or five times the value of the exports, whichever is greater; or for an individual, imprisonment of up to 10 years, or a fine of up to \$250,000 or both.
- 3. In accordance with your certification that establishes you as a "qualified U.S. contractor," unauthorized dissemination of this information is prohibited and may result in disqualification as a qualified U.S. contractor, and may be considered in determining your eligibility for future contracts with the Department of Defense.
- 4. The U.S. Government assumes no liability for direct patent infringement, or contributory patent infringement or misuse of technical data.
- 5. The U.S. Government does not warrant the adequacy, accuracy, currency, or completeness of the technical data.
- 6. The U.S. Government assumes no liability for loss, damage, or injury resulting from manufacture or use for any purpose of any product, article, system or material involving reliance upon any or all technical data furnished in response to the request for technical data.
- 7. If the technical data furnished by the Government will be used for commercial manufacturing or other profit potential, a license for such use may be necessary. Any payments made in support of the request for data do not include or involve any license rights.
- 8. A copy of this notice shall be provided with any partial or complete reproduction of these data that are provided to qualified U.S. contractors.

Qualified requestors may obtain copies of this report from the Defense Technical Information Center, Cameron Station, Alexandria, Virginia 22314-6145. Department of Defense contractors must be established for DTIC services, or have "need to know" certified by cognizant military agency for their project or contract.

DTIC release to NTIS is not authorized.

When U.S. Government drawings, specifications, or any other data are used for any purpose other than a definitely related government procurement operation, the government thereby incurs no responsibility nor any obligation whatsoever; and the fact that the government may have formulated, furnished, or in any way supplied the said drawings, specifications, or any other data is not to be regarded by implication or otherwise, as in any manner licensing the holder or any other person or corporation or conveying any rights or permission to manufacture, use or sell any patented invention that may in any way be related thereto.

Do not return this copy; retain or destroy.

DESTRUCTION NOTICE

For classified documents, follow the procedures in DOD 5220.22.M, Industrial Security Manual, Section II-19 or DOD 5200.1-R, Information Security Program Regulation, Chapter IX. For unclassified, limited documents, destroy by any method that will prevent disclosure of contents or reconstruction of the document.

WARNING

This document contains technical data whose export is restricted by the Arms Export Control Act (Title 22, U.S.C., Sec 2751, et seq.) or The Export Administration Act of 1979, as amended. Title 50, U.S.C., App. 2401, et seq. Violations of these export laws are subject to severe criminal penalties. Disseminate in accordance with the provisions of AFR 80-34.

PREFACE

This report presents the results of a limited subjective evaluation of an aircrew protection ensemble, the Tactical Flight Combat Suit (TFCS), with comparison to an aircrew pressure breathing for g's ensemble flown in the F-16 aircraft. The TFCS was intended to protect aircrew members from high sustained positive acceleration (g), cold water immersion, and heat stress. Testing was conducted at the Air Force Flight Test Center (AFFTC) by the F-16 Combined Test Force using an F-16B aircraft. The

Human Systems Division, Brooks AFB, Texas, requested testing of the TFCS in the F-16B through Program Introduction Document P-88-07-05, 24 June 1988, and testing was conducted in accordance with AFFTC Test Information Sheet FA-1016 (Reference 1).

Thanks to Dorothy Coughlin for all her assistance in the preparation of this technical report.

EXECUTIVE SUMMARY

This report presents the results of a limited evaluation of the Swedish developed Tactical Flight Combat Suit (TFCS). The TFCS was subjectively compared to the unique pressure breathing for g's (PBG) ensemble, the F-16/PBG. A total of five F-16/PBG ensembles had previously been produced exclusively for the F-16 Combined Test Force (CTF) to use in support of high-g loads and performance missions in the F-16.3This test was conducted to evaluate the advantages and disadvantages of the TFCS, in comparison to the F-16/PBG, in the 9 g environment of a high performance fighter aircraft. Ground and flight evaluations were conducted by the F-16 CTF at the Air Force Flight Test Center (AFFTC), Edwards AFB, California from 21 June 1989 to 24 August 1989 at the request of the Human Systems Division (HSD/YAL), Brooks AFB, Texas. There were fifteen flights required to complete the test.

The TFCS used in this test was an integrated life support ensemble designed to provide pilots protection from sustained high-g, cold water immersion, and temperature stress. Components of this modular flight ensemble included a unique lightweight helmet, low profile high pressure oxygen mask, an integrated full coverage anti-g and immersion suit, hoses for suit ventilation, wear protective trousers, and a specialized anti-g/survival vest. The F-16/PBG, a modified derivative of an ensemble previously tested at the AFFTC, was a one-piece flight suit with standard anti-g suit bladder coverage over the lower body, chest counterpressure bladder coverage over the upper torso. and a unique mask and helmet designed to protect pilots from sustained high-g only. The test aircraft was a two-scat F-16B, USAF S/N 81-0816, modified to accommodate either the TFCS or the F-16/PBG. The overall objective was to subjectively evaluate the TFCS in a high-g environment. Ground test objectives included assessing the TFCS for ease of donning and dotfing, mobility, comfort, cockpit fields of view, and functional compatibility with the F-16. Flight test objectives included evaluating the TFCS for anti-g protection, assessing operational cockpit fields of view, cockpit compatibility, and comfort.

The objectives of the TFCS tests were met. In general, the TFCS was more effective than the F-16/PBG in providing aircrews anti-g protection in the sustained high-g environment. It was a significant improvement over the standard issue anti-g suit (CSU-13B/P). The TFCS was bulkier and more restrictive of movement than the F-16/PBG. With design improvements around the joints and waist, freedom of movement could be comparable to the F-16/PBG. Despite the TFCS vapor barrier, the two ensembles caused comparable levels of sweating, due to the effectiveness of the ventilation system of the TFCS. Overall, pilots rated the TFCS helmet and mask better than the F-16/PBG helmet and mask. The TFCS system offered improved fields of view, greater noise attenuation, and both clear and tinted visors. The TFCS lacked the desirable automatic mask tensioning system present in the F-16/PBG helmet and mask. This feature improved mask comfort in-flight because the mask was automatically tightened to the pilot's face during periods of high-g. A significant finding of this test was that anti-g and anti-exposure (immersion) suit features may be successfully incorporated into one flight ensemble. The USAF should pursue the development of a flight ensemble that combines anti-g and anti-exposure protection for use by fighter pilots flying in conditions that currently require the use of the CW-21/P anti-exposure suit.

INTRODUCTION

GENERAL

This report presents the results of a limited subjective evaluation of the Tactical Flight Combat Suit (TFCS). Testing included comparison of the TFCS with a pressure breathing for g (PBG) protection ensemble (F-16/PBG) being used by the F-16 Combined Test Force (CTF) in an F-16C at the Air Force Flight Test Center (AFFTC). The TFCS, a Swedish developed modular flight ensemble, was designed to protect pilots from sustained high positive acceleration (g), cold water immersion, and heat stress. The Swedish Air Force had flown the TFCS to 8 g's. The F-16/PBG was developed by the United States Air Force (USAF) from one of three ensembles previously tested at the AFFTC (References 2 and 3). This unique PBG flight ensemble was made exclusively for the F-16 CTF and consisted of a one-piece flight suit and a unique mask and helmet designed to protect pilots from sustained high-g. The F-16/PBG featured standard anti-g suit bladder coverage to the lower body, but added chest counterpressure bladder coverage to the upper torso for assisted PBG. The Human Systems Division (HSD/YAL), Brooks AFB, Texas, had requested this test to evaluate the TFCS in a 9 g environment in comparison with the F-16/PBG.

Ground and flight tests were conducted by the F-16 CTF at the AFFTC, Edwards AFB, California from 21 June 1989 to 24 August 1989. A two-scat F-16B test aircraft (USAF S/N 81-0816) was modified to accommodate either the TFCS or the F-16/PBG. Front cockpit modifications included a modified g-valve connector, positive pressure breathing system, and a ventilation system. Rear cockpit modifications included a LIFEDATA system (described in Appendix B) in addition to those listed for the front cockpit. Fifteen flights were required to complete the test. Testing the TFCS included donning and doffing, mobility, aircrew comfort, fields of view, anti-g protection, fatigue, and cockpit compatibility. Tests were accomplished in accordance with the Test Information Sheet FA-1016 (Reference 1).

BACKGROUND

During flight in modern high performance aircraft, pilots are often exposed to hazardous environmental conditions such as reduced pressure, hypoxia,

temperature extremes, and high positive g forces. Technological advances have minimized, but not eliminated, the severity of aircrew exposure to many of these hazards (References 4 and 5). Additional improvements are needed to further improve pilots' physiological performance and reduce risks associated with flying high performance aircraft. Advances have already been made in improving anti-g protection and in modifying oxygen systems, and these advanced technologies have received limited aircraft testing (References 2, 3, and 6).

Recently, the USAF has emphasized improving anti-g suit effectiveness by increasing body surface area coverage and by providing life support hardware for assisted positive pressure breathing for g's. Other air forces are likewise investigating methods for evancing life support technology to increase pilots g tolerance. Ensembles are being developed to provide maximum anti-g coverage to the lower body and increased breathing gas pressures (up to 60 millimeters of mercury), delivered to the lungs in conjunction with chest counterpressure provided from an anti-g vest. The effect gained would be balanced internal and external chest pressure, resulting in improved systemic hemocirculation and increased blood-oxygen saturation.

The TFCS tested was an integrated life support ensemble designed to provide pilots protection from sustained high-g, cold water immersion, and temperature stress (Reference 7). Because Swedish Air Force pilots frequently fly their high performance fighter aircraft (ten out of twelve months) while wearing their anti-exposure (immersion) suit, the Swedish Air Force combined the anti-g suit with the anti-exposure suit (the TFCS). The USAF did not have protective gear that combined anti-g and anti-exposure protection in one flight ensemble. The USAF flight gear which came closest to the capability of the Swedish TFCS was the Tactical Air Force (TAF) anti-exposure "poopy" relt (CW-21/P) designed to be worn under the standard anti-g suit. In this ensemble, tactical pilots receive the standard 1950's anti-g protection to the lower body, no ventilation to reduce heat stress, and no assisted positive pressure breathing to enhance g tolerance. For this reason, and the fact that the Tactical Air Command (TAC) continues to report Class A mishaps due to g-induced loss of consciousness (GLOC), HQ/TAC requested that the USAF develop an improved anti-g protection ensemble. This test of the Swedish TFCS provided information for development of a USAF system.

TEST ITEM DESCRIPTION

The modular TFCS was designed to maximize aircrew protection up to 9 sustained g's, provide protection from cold water exposure, and prevent heat stress during extended wear. Components of the TFCS included a unique lightweight helmet, low profile high pressure oxygen mask, an integrated full coverage anti-g and immersion suit, hoses for suit ventilation, wear protective trousers, and a specialized anti-g/survival vest. Figure 1 shows the TFCS ensemble. Illustrations showing a pilot in varying stages of dress in the TFCS ensemble are presented in Appendix A. Inflation of the anti-g/survival vest, for providing chest counterpressure, was controlled by an on/off switch located on the cockpit panel. With this switch in the "on" position, the vest was pressurized with breathing gas from the oxygen regulator, inflating the air bladders in the anti-g vest at aircraft g levels greater than five. When this switch was in the "off" position, the vest did not inflate at any glevel, and the ensemble functioned as a conventional anti-g suit.

An F-16B (S/N 81-0816) aircraft was used for this test. Both cockpits were modified to provide aircrews with PBG, a Fleisch meter to measure breathing gas flow, and a blower for flight suit ventilation. In addition, the rear cockpit was modified to accommodate a stand-alone physiological data acquisition system termed LIFEDATA (Appendix B). Data from the Fleisch flow meters and LIFEDATA were provided to USAFSAM/VNL, Brooks AFB, Texas, and the Swedish Air Force for analysis. The aircraft was flown only with wingtip missiles to maximize sustained 9 g levels. A more detailed description of the aircraft Class II modification is presented in Appendix B.

TEST OBJECTIVES

The overall objective was to subjectively evaluate the TFCS in a sustained high-g operational environment in comparison to the F-16/PBG. Specific ground test objectives were to evaluate:

- 1. case of donning and doffing,
- mobility during cockpit ingress and egress,
- 3. pilot comfort during proflight inspection,
- 4. fields of view inside both cockpits, and
- 5. functional compatibility with the F-16.

Specific flight test objectives were to evaluate:

- 1. anti-g protection,
- 2. fields of view outside both cockpits,
- 3. comfort in flight,
- 4. capability to perform routine and simulated combat flight operations,
 - 5. the TFCS ventilation system, and
- to collect inflight physiological data for analysis by medical experts from Brooks AFB, Texas, and the Swedish Air Force.

CONSTRAINTS AND LIMITATIONS

Nonavailability of some TFCS components and sizes made it impossible to properly fit two of the three AFFTC test pilots. Pilot B did not have a custom fit TFCS ensemble, so he used one of the Swedish pilots' TFCS mask and helmet, and another's TFCS garment. This AFFTC pilot wore his F-16/PBG mask and helmet with the TFCS garment when he flew in the front cockpit, and this Swedish pilot was in the rear cockpit during the same test flight. Pilot C had a custom fit TFCS garment, but was unable to attain an airtight scal with the TFCS mask even though he had previously been measured and fitted by Swedish life support personnel. Components needed to modify the mask to achieve the proper mask fit for pilot C were not available at the AFFTC. Therefore he used his F-16/PBG mask and helmet with the TFCS garment in place of the TFCS mask and helmet.

The TFCS had four basic features. It featured improved anti-g capability, assisted positive pressure breathing for g protection, anti-exposure protection, and air ventilation to prevent heat stress. The one-piece F-16/PBG had one additional feature that was

different from the standard anti-g suit. It had assisted positive pressure breathing for g protection. The TFCS was significantly more complex and had more components than the F-16/PBG, and this difference should not be lost in the analysis comparing the

comfort and mobility of the two ensembles. The configuration of the ensembles would have been more equal if the test subjects could have worn the CW-21/P "poopy" suit under the F-16/PBG. Poopy suits were not available to use with the F-16/PBG.

Figure 1 Tactical Flight Combat Suit

This page intentionally left blank.

TEST AND EVALUATION

Overall the test activities consisted of subjectively evaluating the Tactical Flight Combat Suit (TFCS) during aircraft ground operations and during 11 sorties which emphasized sustained high-g test points and aerial combat maneuvers/basic fighter maneuvers (ACM/BFM).

Three AFFTC pilots qualified and experienced in pressure breathing for g's flew the TFCS in varying configurations. Pilot A had a well-fitted, customized TFCS ensemble. Pilot B had not been scheduled carly-on as one of the AFFTC test pilots supporting this test. As a result, a customized TFCS was not available for his use. Pilot C had previously been measured for a complete customized TFCS. He was, however, unable to attain a proper mask fit/scal while wearing his TFCS mask and helmet so he wore his F-16/PBG mask and helmet instead.

Ground testing of the TFCS was performed to ensure cockpit compatibility prior to flight test. Two AFFTC pilots tested the TFCS for system design during preflight inspection of the aircraft and assessed its integration within the cockpit. Each pilot assessed the following:

- 1. case of donning and doffing,
- 2. mobility during preflight inspection and cockpit ingress/egress,
- 3. comfort with respect to heat, pinching, or binding points,
 - 4. fields of view inside front and rear cockpits,
 - 5. visor distortion, glare, and reflection, and
 - 6. the ventilator, g-valve, and oxygen regulator.

Each AFFTC pilot flew at least one familiarization (FAM) sortic wearing the TFCS to become familiar with the ensemble in the F-16 cockpit prior to participating in the sustained high-g test flight profiles.

The flight test matrix and flight test profiles are shown in Appendix C.

The intent of the test matrix was to exercise the TFCS in the sustained high-g and ACM/BFM flight environments. This allowed the pilots, based on their experience flying in the F-16/PBG, to assess their performance in the TFCS relative to the F-16/PBG under high-g conditions, where combat suits would be needed most. The following were evaluated in flight:

- 1. fit.
- 2. reach and mobility,
- 3. comfort.
- 4. fields of view inside and outside the cockpit,
- 5. visor distortion, glare, reflections, and
- 6. anti-g protection.

Pilots completed subjective questionnaires following each flight. The questionnaires and pilot responses are included in Appendix D.

TEST RESULTS

The objectives of ground and flight tests were met. In general, the TFCS was more effective than the F-16/PBG for providing aircrews anti-g protection in the sustained high-g environment. The TFCS provided significant improvement in anti-g protection relative to the standard (CSU-13B/P) anti-g suit. The USAF should develop a full coverage anti-g suit for pilots flying in high performance aircraft. (R1)

While pilot consensus was that the TFCS was more effective than the F-16/PBG in sustained high-g environments, it was bulkier and more restrictive of movement than the F-16/PBG. With design imprevements around the pilot's joints and waist, freedom of movement could be comparable to the

Numerals preceded by an R within parentheses at the end of a paragraph correspond to the recommendation numbers tabulated in the Conclusions and Recommendations section of this report.

F-16/PBG. Despite the TFCS vapor barrier, the two ensembles caused comparable levels of sweating, due to the effectiveness of the ventilation system of the TFCS. Overall, pilots rated the TFCS helmet and mask slightly better than the F-16/PBG helmet and mask, The TFCS system offered improved fields of view. greater noise attenuation, and both clear and tinted visors. The TFCS lacked the desirable automatic mask tensioning system present in the F-16/PBG helmet and mask. This feature improved mask comfort in flight, because the mask was automatically tightened to the pilot's face only during periods of high g. A significant finding of this test was that anti-g and anti-exposure suit features may be incorporated successfully into a single effective flight ensemble. The USAF should pursue the development of a flight ensemble that combines anti-g and anti-exposure protection for use by fighter pilots flying in conditions that currently require the use of the CW-21/P anti-exposure suit. (R2)

Ground Test:

Table 1 summarizes pilot subjective evaluations made during ground testing of the TFCS in comparison to the F-16/PBG. Ground test questionnaire responses are presented in Appendix D.

Putting on the TFCS for the first time was difficult due to the unfamiliarity and bulkiness of the ensemble. The subjective ratings in Table 1 regarding the donning/doffing of the TFCS were made shortly after the pilots first attempted wearing the protective gear. At the end of the flight test, the pilots were donning and doffing the TFCS easily, usually within five to ten minutes.

The fact that the pilots rated the F-16/PBG better relative to the TFCS for donning and doffing was anticipated because of the complexity of the TFCS. It had more features and components, and was, therefore,

Acceptability for Plight		x	

more complicated to wear. Because the TFCS was fitted snugly for maximum effectiveness, it was difficult to flex and extend the joints. For this reason, flight boots were more difficult to put on and lace up. The anti-g vest, worn over the immersion suit, was easy to don and doff.

While pilot A expressed no problems with donning the TFCS helmet, pilot B, who shared a TFCS helmet and mask with a Swedish pilot, reported difficulty in donning the TFCS helmet. Donning the IFCS helmet was accomplished by using the thumbs to spread the opening of the helmet at the edge of the carcups and moving the helmet forward in an oblique back-to-front plane, rather than in the top-to-bottom plane as was customary with the F-16/PBG helmet. The TFCS helmet was specifically designed to fit snugly against the angle of the jaw and beneath the car to prevent it from being pulled from the pilot's head under wind blast typical of ejection. It lacked a chin strap for securing it to the pilot's head (see Appendix A, Figure A3). Pilot A, fitted with his own TFCS helmet, four 'it was better than his F-16/PBG helmet. Both pilots found the TFCS mask more comfortable than the F-16/PBG mask.

Pilots had to adjust the r parachute harness when donning it over the bulkier TFCS. The ensemble's restrictiveness made preflight ground inspection of the aircraft, cockpit ingress and egress, and movement within the cockpit more difficult than when wearing the F-16/PBG. Pilot A experienced discomfort in the knees when inspecting the aircraft wheel wells (Figure 2). During ingress, restriction in range of motion at the knee joint made it difficult for the pilots to prevent their boots from hitting the instrument panel. In the cockpit, upper torso rotation and suit bulk made it difficult for the pilots to connect their anti-g and ventilation hoses.

The point of attachment of the oxygen supply hose to the TFCS anti-g vest interfered with the parachute harness chest buckle during strap-in. Dependent upon torso length and personal preference, pilots had to either fasten the parachute harness buckle under or over this vertical oxygen tube (Figure 3). Figure 4 shows the parachute harness buckled under the vertical oxygen tube to the anti-g vest. Furthermore, the fixed hose attachment to the anti-g vest was located too close to the chin, causing interference with head movement (Figure 4). The F-16/PBG had a swivel connection located lower on the chest and further away from the

chin, allowing for less restrained oxygen hose and head movements.

Connection fittings for attaching the oxygen hose to the anti-g vest and mask should swivel and be relocated further away from the chin. This would reduce the likelihood of the hose interfering with head movement. USAF pressure breathing for g protection developmental programs should make the vertical oxygen hose anti-g vest attachment a swivel type connection located away from the pilot's chin. (R3)

The profile of the TFCS mask allowed pilots a slightly larger field of view within the cockpit relative to the F-16/PBG mask. Figures 5 and 6 illustrate a 95th percentile (sitting height) pilot's front and rear cockpit fields of view respectively, while sitting at his usual in-flight scat position, looking at the HUD, and wearing the different masks. The areas under the hash marks denote areas obscured from the pilots view by the mask. Similarly, a 86th percentile (sitting height) pilot drew his front (Figure 7) and rear (Figure 8) cockpit fields of view while wearing the two different masks. Again the area under the hash marks denotes areas obscured from view by the masks. Both pilots indicated that the TFCS mask improved cockpit field of view. However this improvement was somewhat offset by the bulk of the wear protective trousers worn over the anti-g/immersion suit, which slightly obscured the view of the landing gear handle and some of the cockpit caution lights. No glare or reflections were caused by the test items during ground testing. When the pilots performed the emergency ground egress procedures, they reported that the difficulty of egress was similar for the two suits. All quick disconnecting lines functioned properly, and posed no apparent safety hazard to the aircrews which could occur in the event of an actual ground emergency.

Because the F-16/PBG was less restrictive and less bulky, it was more comfortable than the TFCS when wearing it outside the cockpit. No uncomfortable binding or pinching points were noted while wearing the TFCS in the cockpit. The TFCS and F-16/PBG were considered to be equally comfortable in the cockpit. Despite the added vapor barrier component layer of the TFCS, perceived level of sweating was the same with both ensembles. The blower (ventilator) ventilated the TFCS effectively, in general circulating cool air to the body and improving the overall comfort experienced with the TFCS. Although cooling air was distributed to all parts of the body, sweating was more

noticeable in the lower abdomen, back, and arms. The blower did not distract the pilots during ground testing. All TFCS system components functioned properly in conjunction with the aircraft Class II modification in both cockpits.

Flight Test:

Table 2 summarizes the pilots' subjective evaluations of the TFCS relative to the F-16/PBG during flight test. Responses to flight test questionnaires are presented in Appendix D.

Three AFFTC test pilots flew the TFCS in the test aircraft. Of these three, pilots A and B flew the TFCS in both the front and rear cockpits. Pilot C flew in the front cockpit only, wearing the F-16/PBG helmet and mask and the TFCS garment because he was unable to obtain a proper oxygen mask-to-face seal with the TFCS mask.

The most favored feature of the TFCS was its effective anti-g protection. Even though the flight test profiles (see Appendix C) included a number of sustained high-g points, pilots returned to base feeling only slightly fatigued. The pilots reported no turnel vision at any test point when the assisted positive pressure breathing system was operating correctly. Pilots B and C reported experiencing tunnel vision, up to 50 percent and 20 percent respectively, during the 7 g point of the g warm-up maneuver. All pilots returned to base feeling slightly fatigued, although each asserted that he felt significantly better than he would have

without the benefit of assisted positive pressure breathing for g's.

The pilots who wore the complete TFCS ensemble found the TFCS helmet and mask provided better overall visibility relative to the F-16/PBG helmet and mask. Noise attenuation provided by the TFCS carcups and helmet, even without using the foam car inserts for noise protection, was highly effective. During test flights, the pilots found the use of foam car defenders unnecessary, and they were not used. Pilot A felt the TFCS helmet was more comfortable than the F-16/PBG helmet, while pilot B rated them about the same. Pilot C never wore the TFCS helmet or mask. Pilot A was the only AFFTC pilot to fly with a customized TFCS helmet and mask.

Unlike the F-16/PBG helmet, the TFCS helmet lacked an automatic mask tensioning system for tightening the mask to the face during periods of sustained high g. Although the TFCS mask was rated better overall, the lack of an automatic mask tensioning device made it impossible to achieve a balance between comfort and fit to prevent breathing gas leaks at high g's. USAF pressure breathing for g protection developmental programs should include the incorporation of an automatic oxygen mask tensioning system. (R4)

Bulkiness was the greatest drawback of the TFCS, causing annoyances in several areas, but it did not interfere with the pilot's ability to safely operate the aircraft. These areas of annoyance included restricted.

Table 2

SUMMARY OF FLIGHT TEST RESULTS

COMPARING THE TFCS WITH THE F-16/PBG

Evaluation Area	F-16/PBG Better	Equal	TFCS Better
Anti-g Protection - TFCS			x
Aircrew Performance - Cockpit operation		х	
Aircrew Comfort - Pinching and binding - Helmet and mask - Itching points - Sweating		x x	X X

torso mobility, limited reach, and control stick interference. While freedom of movement was more restrictive within the cockpit, pilot A found it was easier to look over his shoulder to "check six" with the TFCS. Pilots B and C found checking six more difficult relative to the F-16/PBG. The latter two pilots disliked the mobility restriction imposed upon them when twisting their torso during ACM/BFM. All pilots noted their reach within the cockpit was more limited when wearing the TFCS than when wearing the F-16/PBG. They found it difficult to operate some cockpit switches and controls. Pilot A, who flew with the seat raised nearly to its maximum height, noted that TFCS right leg garment inflation interfered with the flight control stick (Figures 9 and 10). When rapidly attaining and sustaining high-g's, anti-g suit inflation, in conjunction with the already ballooned wear protective trousers (due to the ventilation system), caused lateral stick acflection, resulting in an unexpected right roll. This phenomenon has occurred in the Tactical Air Force with pilots wearing the standard issue anti-g suit. Although undesirable, the pilot compensated for this deficiency once it was identified.

Similar to ground test, the point of attachment of the oxygen supply hose to the TFCS anti-g vest caused difficulties for Pilot A. The fixed oxygen hose attachment to the anti-g vest, located close to the chin, caused interference with head movements and resulted in a sharp bend in this hose which caused it to collapse under high-g. Tape had to be wrapped around his oxygen hose at this bend to prevent it from collapsing and restricting breathing gas flow to the mask under high-g.

The use of swivel connection fittings for attaching the oxygen hose to the anti-g vest and relocation of this connection to a point further from the chin would reduce the likelihood of the hose interfering with head movement and would lessen bend curvatures in the oxygen hose, thus reducing the tendency for the hose to collapse at high-g levels. The USAF pressure breathing for g protection developmental programs should make the vertical oxygen hose anti-g vest

attachment a swivel type connection located away from the pilot's chin. (23)

The flexible senselines in both cockpits functioned correctly after the Class II modification. During the second flight, the front cockpit pilot noticed less pressure in his PBG mask relative to his previous PBG experience. Aircraft vibration and/or g forces had caused the senseline in the front cockpit to become pinched under the map case. To eliminate possible constriction and loss of signal, future designs should avoid the use of a flexible pneumatic senseline between the g-valve and oxygen regulator. (R.5)

Testing showed that pilot comfort in the cockpit was dependent upon suit fit. While wearing the TFCS, the pilots noted proper arrangement of their underwear and flight suit components prior to ingressing the cockpit was necessary for flight comfort. The TFCS, particularly its anti-g suit component, covered more body area with inflatable bladders. The importance of fit was reflected in the increased bladder coverage.

The air ventilation system of the TFCS was effective in cooling the pilots, even at lower flow settings. Although the amount of air delivered to the suit by the blower could be adjusted during flight, most pilots left the control valve in the fully open position. Regardless of the flow setting, pilot observation indicated that ventilation was not uniformly distributed to all parts of the body. This was not objectionable. Most of the sweating in the TFCS occurred during ground operations prior to closing the canopy. The significance of this result showed that, relative to heat stress, a full coverage anti-g/immersion suit with PBG capability could be as comfortable as the standard anti-g suit. The blower itself did not distract the pilots in-flight.

Pilots A and B reported that they would use the TFCS on every high-g or ACM/BFM sortie. Pilot C preferred his F-16/PBG over the TFCS, because it was not as bulky and was less restrictive of movement while in or out of the cockpit.

Figure 10 Inflated TFCS

CONCLUSIONS AND RECOMMENDATIONS

The overall objective was to subjectively evaluate the Tactical Flight Combat Suit (TFCS) in a sustained high-g operational environment in comparison to the F-16/PBG. This objective was fully met by this test.

High-g test flight profiles showed the TFCS was more effective in providing pilots enhanced g protection than the F-16/PBG. The TFCS was a significant improvement for enhancing anti-g protection relative to the standard issue anti-g suit.

1. The USAF should develop a full coverage anti-g suit for pilots flying in high performance aircraft. (Page 5)

A significant finding of this test was that anti-g and anti-exposure suit features may be successfully incorporated into one operationally effective flight ensemble.

2. The USAF should pursue the development of a flight ensemble that combines anti-g and anti-exposure protection for use by fighter pilots flying in conditions that currently require the use of the CW-21/P anti-exposure suit. (Page 6)

Putting on the TFCS for the first time was difficult due to the unfamiliarity and bulkiness of the ensemble. The TFCS was complex and more time was required to don all its components. However, by the end of flight test, pilots were easily donning and doffing the TFCS. Familiarity with the TFCS in the cockpit also improved as the test progressed. Still, the fixed point of attachment of the oxygen supply hose to the g-vest interfered with cockpit mobility and head movement because it was located too close to the pilot's chin. It also caused a sharp bend in the oxygen hose, causing it to collapse under high g's. The F-16/PBG had a swivel connection which allowed freer oxygen hose and head movement, and was located further away

from the chin. A swiveling attachment located a little further away from the chin would reduce the likelihood of the hose interfering with head movement or collapsing during high-g points.

3. The USAF pressure breathing for g protection developmental programs should make the vertical oxygen hose anti-g vest attachment a swivel type connection located away from the pilot's chin. (Pages 7 and 16)

There were significant differences between the TFCS and F-16/PBG masks and helmets. The TFCS mask itself was rated better overall. The TFCS mask and helmet provided pilots with an increased field of view, highly effective noise attentuation, and both clear and tinted visors. Unlike the F-16/PBG helmet, the TFCS helmet lacked an automatic mask tensioning system for tightening the mask to the face during periods of high g. This required the pilots to keep the mask uncomfortably tight all the time in order to prevent breathing gas leaks at high g.

4. The USAF pressure breathing for g protection developmental programs should include the incorporation of an automatic oxygen mask tensioning system. (Page 15)

Aircrast vibration and/or g forces caused the senseline running from the g-valve to the oxygen regulator in the front cockpit to work under the map case, pinching the senseline between it and the aircrast. Constriction of this senseline caused a loss of the pneumatic signal being sent to the oxygen regulator which then failed to provide the pilot with proper PBG protection.

5. To eliminate possible constriction and loss of signal, future designs should avoid the use of a flexible pneumatic senseline between the g-valve and oxygen regulator. (Page 16)

APPENDIX A TFCS AND F-16/PBG SYSTEMS DESCRIPTION

This page intentionally left blank.

TFCS AND F-16/PBG SYSTEM DESCRIPTIONS

FUNCTIONAL OVERVIEW OF EACH SYSTEM

The modular Tactical Flight Combat Suit (TFCS) included a lightweight helmet, low profile oxygen mask, combined ventilated anti-g and immersion suit, wear protective trousers, and a specialized anti-g/survival vest. The F-16/PBG included a one-piece flight suit, low profile oxygen mask, and a unique helmet. The F-16/PBG featured the same anti-g suit bladder coverage as the standard CSU-13B/P anti-g suit worn by USAF pilots flying aircraft equipped with a g-valve. Inflatable chest bladders were incorporated into the upper portion of each ensemble. When at greater than 5 g's, the oxygen regulator supplied assisted positive pressure breathing gas to the mask, inflating the air bladders covering the chest for balanced chest counterpressure. Both systems provided protection to aircrews from sustained high-g.

COMPONENTS

Figure A1 shows a photograph of the TFCS and F-16/PBG helmets and masks. This comparison of the helmet/mask assemblies illustrates differences in the two systems. The TFCS helmet was shorter and wider than the F-16/PBG. The TFCS assembly had standard offset bayonent connectors to attach the oxygen mask to the helmet while the F-16/PBG assembly did not. Also the mask dropped from the right side (left side hinge) with the TFCS assembly, and the intercom cord was on the left, while the mask dropped from the left side (right side hinge) with the F-16/PBG assembly, and the intercom cord was on the right. Note the single visor control knob on the F-16/PBG (visor movement was accomplished on the left) helmet while the TFCS helmet had symmetrical visor control knobs which moved two different visors.

An oblique view of each helmet is shown in Figure A2. The facial openings, visor adjusting knobs, and the carcup designs were different for the two helmets. Also the TFCS helmet lacked a chin strap but had both clear and tinted visors.

A bettom view (Figure A3) shows that the TFCS helmet was slightly shorter than the F-16/PBG helmet in the front-to-back plane. Also the lower front margin of the TFCS curved inward, providing a snug fit at the

mandibular angle of the lower jaw. An automatic mask tensioning bladder was in the back of the F-16/PBG helmet.

Figures A4 and A5 show front views of a test pilot wearing the TFCS and F-16/PBG helmets and masks, respectively. Mask profiles, microphone and intercom attachments, and oxygen hose routings were different for the two masks. The hose attaching to the left side of the TFCS mask was used during testing to measure breathing gas pressures in the mask.

Figures A6 through A9 show the right and left sides of the two helmet/mask assemblies. The difference in the frontal projection of the two masks is illustrated in Figure A10. The F-16/PBG mask is deeper and extends further from the face.

Elight suits were significantly different. Figure All shows a test pilot wearing the F-16/PBG. This unique ensemble, designed to provide pilots protection from sustained high-g, had laces in the legs and torso areas for a snug fit. The suit had the standard anti-g suit bladder coverage to the lower body and the hose which connected into the g-valve located in the cockpit. The oxygen hose connected to the CRU-60/P which was located on the parachute harness. It had a swivel attachment to the anti-g vest portion of the ensemble that covered the torso enroute to the mask. The anti-g suit functioned independently of the anti-g vest and mask below 5 g's. At 5 g's and greater, the g-valve sent a proportionate pneumatic signal to activate the oxygen regulator to proportionately increase breathing gas output to the anti-g vest, automatic mask tensioning bladder, and the mask.

The Tactical Flight Combat Suit (TFCS) was a modular flight suit designed to provide pilots protection from sustained high-g's, cold water immersion, and heat stress.

Pilots were underwear to protect their skin from chaffing, and to wick perspiration away from the skin. The anti-g/immersion suit component of the TFCS was donned first. This component was donned while in a seated position (Figure A12). It had anti-g biadders incorporated into the impervious layer of the

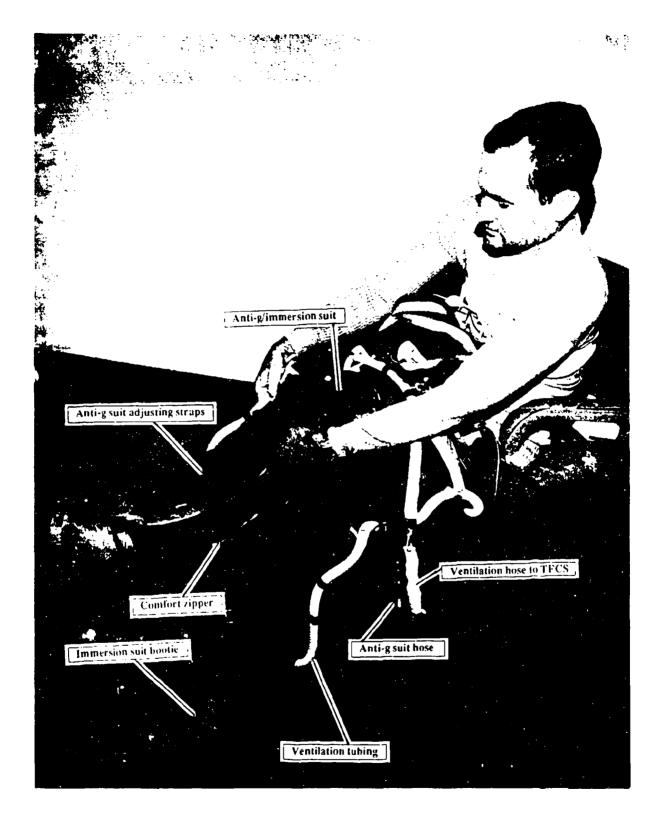

Figure A12 Pilot Donning Anti-g/Immersion Suit of TFCS

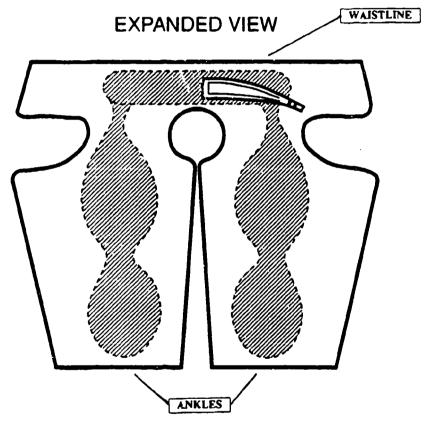

anti-exposure suit. The anti-g suit bladder coverage was greater than that of the standard anti-g suit (Figure A13). The booties of the anti-exposure suit did not contain anti-g bladders. Numerous adjustable straps were located down the legs for an effective fit to maximize anti-g protection. The plastic tubing along the lateral length of the suit provided ventilated air to the legs. Comfort zippers, opened when donning the suit and flight boots, were located along the medial length of each leg. These zippers were closed prior to donning the wear protective trousers. To don the upper portion of the anti-exposure suit, the pilot placed his head through a rubberized hole in the central flap of the suit and zipped it closed (Figure A14). Plastic ventilation tubes were located along the sides of the upper portion of the anti-exposure suit for cooling the lorso.

After securing the anti-g/exposure suit, the pilot donned the wear protective trousers (WPT). Zippers were located along the inside length so pilots could don

this garment while wearing flight boots. The WPT protected the ventilation tubes and reduced the risk of snagging the anti-g suit adjustable straps (Figure A14). The anti-g suit connecting hose and the ventilation hose were routed through a slit in the left side of the WPT. Figure A15 shows the back of the WPT fitted on the pilot.

Next the pilot donned the anti-g/survival vest which contained air bladders to provide chest counterpressure during periods of positive pressure breathing. It was important that the anti-g vest fit snugly to the pilot. To accomplish this, the anti-g vest had adjustable laces on each side (Figure A16). The design of these laces permitted rapid alterations when the vest was worn by more than one pilot or over a flight jacket. A front view of the ensemble, with the pilot wearing the helmet and mask, is shown in Figure A17. This photograph shows the pilot attached to the portable blower used to ventilate the TFCS on the ground prior to cockpit ingress.

APPENDIX B AIRCRAFT CLASS II MODIFICATIONS

AIRCRAFT CLASS II MODIFICATIONS

Table B1 lists the components included in the aircraft Class II modification.

Aircrast F-16B, S/N 21-0816, was modified to support this test. Both cockpits were modified to accommodate a Clifton Precision modified CRU-73/A oxygen regulator. The regulators were modified by the manufacturer with internal relief valves for venting excessive back-flow pressures. As a result of this internal modification, the integrity of these regulators was not testable by standard Technical Order procedures. Attached to the back of each regulator was an electrical solenoid. The solenoid was opened or closed by a PBG switch located on the cockpit panel (Figure B1). With the PBG switch in the "off" position, the oxygen regulator would not deliver breathing gas at pressures greater than the standard CRU-73/A oxygen regulator. Figure B1 also shows the mechanical PBG control valve designed into the Class II modification package as a safety feature. When this mechanical valve was opened (counter clockwise rotation), air was allowed to flow through a senseline connecting the g-valve to the oxygen regulator. Closing the valve stopped the flow of air.

The senseline mentioned above was a flexible tube installed between the g-valve and the oxygen regulator for the purpose of sending a pneumatic signal from the g-valve to the oxygen regulator (Figure B2). Pressure transducers were located in-line, one near the g-valve, and one near the oxygen regulator. These transducers

sensed pressure levels, first in the g-valve, and then in the oxygen regulator. With the proper pressure signal from the g-valve (based on g input), the oxygen regulator would increase its breathing gas pressure output to the pilot at pressure levels greater than normal but less than 60 mm Hg. Because of this pressure sensing system between the g-valve and the oxygen regulator, a 3/8 inch diameter hole was drilled into the check valve located in the anti-g suit hose connectors. With this hole in the check valve, the flow of air was unrestricted through the connector.

A ventilation system was installed in each cockpit to provide cooling air to pilots wearing the TFCS. This system included a blower motor controlled with an electrical "on/off" switch and connecting hose. The blower (fan) was located near the anti-g valve (Figures B3 and B4) so that the anti-g hose and ventilator hose would be bound together in the cockpits. The ventilator hose attached to the TFCS via a slip connector. This connector contained a sliding control valve which permitted the pilot to regulate the flow of cooling air into the suit.

Fleisch flow meters were installed under the right side panels in-line between the oxygen regulator and the pilot (Reference 8). Figure B5 shows the flow meter during installation. The flow meters measured and monitored the rate and depth of the pilot's breathing throughout the flight. This signal was recorded on the aircraft analog data tape.

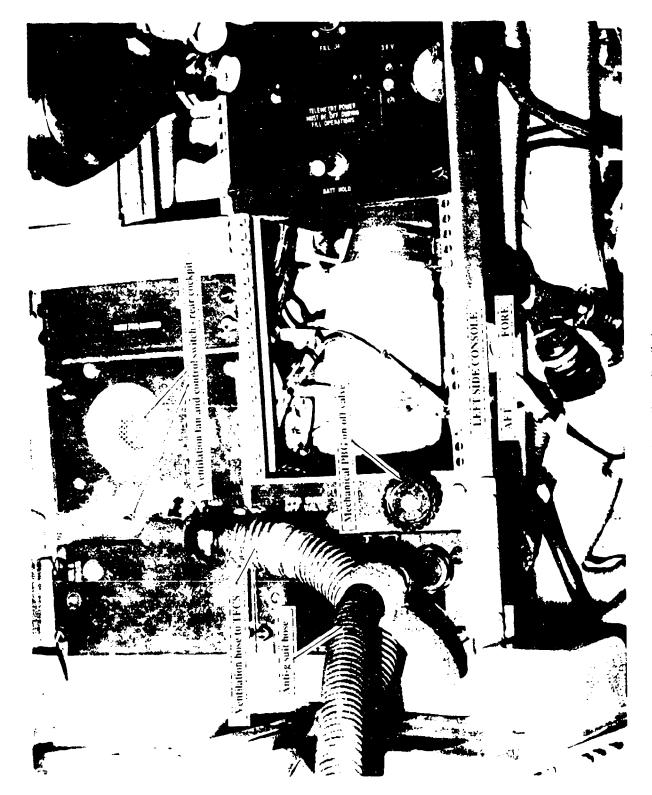

Figure B4 - Ventilator Fan and Hose in Rear Cockpit

LIFEDATA, the Swedish stand-alone physiological data collection system, was installed in the rear cockpit only. This system consisted of a box of computer boards and integrated circuits (Figure B6) mounted in the right rear side panel. A Sony audio cassette tape recorder with an "on/off" switch was mounted in the left console (Figure B7) to record the physiological data collected during the flight. Sensing

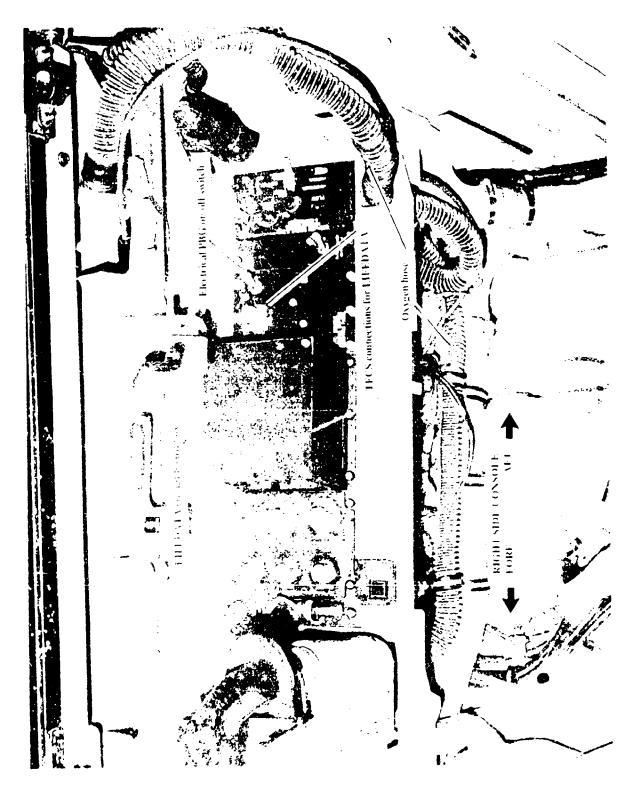

devices were placed on test pilots with electrical leads attached to a plug-in connector on the right side panel of the aircraft.

Aircrast parameters measured and recorded for use by USAFSAM/VNL, Brooks AFB, Texas, and the Swedish Air Force are listed in Table B2.

NOTES: Numbers represent number of flights per pilot.

• Pilots flew with standard anti-g suit, CSU-13B/P.

•• Pilots flew with PBG off.

PROCEDURES FOR FLIGHT TEST

G-1 G WARM-UP MANEUVER

Perform 4 g and 7 g turns for the g warm-up maneuver before commencing the test runs.

G-2 SUSTAINED G TURN

Perform a turn at the target g level. Hold g's through 180 degree heading change.

G-3 WIND-UP TURNS

Initiate a turn. Increase load factor at a rate of 2 g/sec to target g and hold for 10 seconds.

G-4 ABRUPT PULL-UP

Perform an abrupt, full aft stick pull-up, recovering at 60 degrees of pitch or 250 KCAS, whichever occurs first.

G.5 TURN REVERSAL

Begin a turn at the indicated g level, altitude and airspeed. Perform an abrupt turn reversal, not exceeding the A/C asymmetric limit.

G-6 SLICE-BACK

Establish initial conditions. With power set for level flight, roll to 135 degrees of bank and abruptly apply aft stick as necessary to maintain 6 g's. Hold for 180 degrees of heading change.

G-7 OFFENSIVE PERCH (LOW SPEED)

Low speed offensive perch engagements will occur at altitudes as required to stay above 5000 AGL, at speeds ranging from 250 knots to 350 knots, and at normal acceleration levels ranging from 4 to 6 g's with the test A/C attacking a cooperative target. The target A/C will turn on the test A/C's call. The test A/C will use whatever maneuvers are needed to close for simulated missile shot (FOX II). The exercise will be terminated if neutrality between A/C is achieved or there are two successive valid shots.

G-8 OFFENSIVE PERCH (HIGH SPEED)

High speed offensive perch engagements will occur at altitudes as required to stay above 5000 AGL, at speeds ranging from 400 knots to 550 knots, and at normal acceleration levels ranging from 6 to 9 g's with the test A/C attacking a cooperative target. The target A/C will turn on the test A/C's call. The test A/C will use whatever maneuvers are needed to close for simulated tracking guns shot. The exercise will be terminated if neutrality between A/C is achieved or there are two successive valid shots.

PROCEDURES FOR FLIGHT TEST (Concluded)

G-9 DEFENSIVE PERCH (LOW SPEED)

Low speed defensive perch engagements will occur at altitudes as required to stay above 5000 AGL, at speeds ranging from 250 knots to 350 knots, and at normal acceleration levels ranging from 4 to 6 g's with a cooperative target A/C attacking the test A/C. On the target A/C's call, it will attempt to close on the test A/C for simulated missile shot (Fox II). The test A/C will use whatever maneuvers are necessary to negate the attack. The exercise will be terminated if neutrality between A/C is achieved or there are two successive valid shots.

G-10 DEFENSIVE PERCH (HIGH SPEED)

High speed defensive perch engagements will occur at altitudes as required to stay above 5000 AGL, at speeds ranging from 400 knots to 550 knots, and at normal acceleration levels ranging from 6 to 9 g's with a cooperative target A/C attacking the test A/C. On the target A/C's call, it will attempt to close on the test A/C for simulated tracking guns shot. The test A/C will use whatever maneuvers are necessary to negate the attack. The exercise will be terminated if neutrality between A/C is achieved or there are two successive valid shots.

G-11 NEUTRAL ENGAGEMENT

Neutral engagements will occur at altitudes as required to stay above 5000 AGL, at speeds ranging from 250 knots to 550 knots, and at normal acceleration levels ranging from 4 to 9 g's with a cooperative target A/C. On the test A/C's call, the two A/C will separate and begin the engagement as prebriefed. Each A/C will maneuver as required to gain the advantage for either simulated missile shot (Fox II) or tracking guns shot. Each A/C will use whatever maneuvers are necessary to negate the maneuvers of the attacking A/C. The exercise will be terminated if neutrality between A/C is achieved or there are two successive valid shots.

FLIGHT TEST CONDITIONS

ALL FAM FLIGHTS AND THE FCF

Run No.	Conditions	Maneuver	Procedures
1	4 g's/7 g's	g Warm-Up	G-1
2	3 g's/0.8M	Sustained g Turn	G-2
3	5 g's/0.8M	Sustained g Turn	G-2
4	7 g's/0.8M	Sustained g Turn	G-2
5	8 g's/0.8M	Sustained g Turn	G-2
6	9 g's/0.9M	Sustained g Turn	G-2
7	7 g's/0.8M	Wind-Up Turn	G-3
8	8 g's/0.8M	Wind-Up Turn	G-3
9	Max g/0.8M	Abrupt Pull-Up	G-4
10	Max g/0.9M	Abrupt Pull-Up	G-4
11	3 g's/0.5M	Turn Reversal	G-5
12	4 g*s/0.5M	Tum Reversal	G-5
13	6 g*s/0.8M	Slice Back	G-6

- 1. Maintain Mach and altitude as required to sustain desired g-level.
- 2. Except for optional wingtip missiles, all stations clean.
- 3. Check "six" often to establish baseline for future comparisons.
- 4. Air refuel as required.

ACM/BEM

Run No.	Conditions	Maneuver	Procedures
1	4 g's∏ g's	g Warm-Up	G-1
2	4-6 g's	Offensive Perch (Low Speed)	G-7
3	6-9 g's	Offensive Perch (High Speed)	G-8
4	4-6 g's	Defensive Perch (Low Speed)	G-9
5	6-9 g's	Defensive Perch (High Speed)	G-10
6	4-9 g's	Neutral Engagement	G-11

- 1. All maneuvers will be terminated so that the A/C will be recovered to level flight by 5,000 AGL.
- 2. Maintain Mach and altitude as required to sustain desired g-level.
- 3. Except for optional wingtip missiles, all stations clean.
- 4. Prebrief all "knock it off" criteria.
- 5. Air refuel as required.
- 6. Repeat engagements as necessary.
- 7. All runs targeted for one successful completion; repeat run 6 a maximum of four (4) times.

HIGH-G/DURATION (TARGET 2+HRS)

Run No.	Cunditions	Maneuver	Procedures
1	4 g's/7 g's	g Warm-Up	G-1
2	7 g's/0.8M	Sustained g Turn	G-2
3	7 g's/0.9M	Sustained g Turn	G-2
4	8 g's/0.8M	Sustained g Turn	G-2
5	8 g's/0.9M	Sustained g Turn	G-2
6	9 g's/0.9M	Sustained g Turn	G-2
7	6 g's/0.8M	Stice Back	G-6
8	7 g's/0.8M	Wind-Up Turn	G-3
9	8 g's/0.8M	Wind-Up Turn	G-3
10	Max g/0.8M	Abrupt Pull-Up	G-4
11	Max g/0.9M	Abrupt Pull-Up	G-4
12	3 g's/0.5M	Elevated g Roll	G-5
13	4 g's/0.5M	Elevated g Roll	G-5

- 1. Repeat runs 2 through 13 as often as necessary to attain target time.
- 2. Mission duration targeted for more than 2 hours but should not exceed 2.2 hours.
- 3. Maintain Mach and altitude as required to sustain desired g-level.
- 4. Except for optional wingtip missiles, all stations clean.
- 5. Check "six" as required.
- 6. Air refuel as required.
- 7. Rest as needed between test runs.
- 8. If fatigued prior to completing card, "knock it off" and return to base.
- 9. Provision for water in a plastic water bottle.
